

Incorporating Female Reproductive Development Into Voltinism Studies

Anne L. Nielsen

Rutgers University

Shelby Fleischer and Mike Saunders

Pennsylvania State University

How can we best predict the number of generations?

- DD requirements for development (538, base 14°C)
- DD requirements of reproductive maturation? (148 DD)
- Complicated phenology:
 - Long lifespan
 - Overlapping generations
 - Diapausing adult stage
 - Need an appropriate biofix

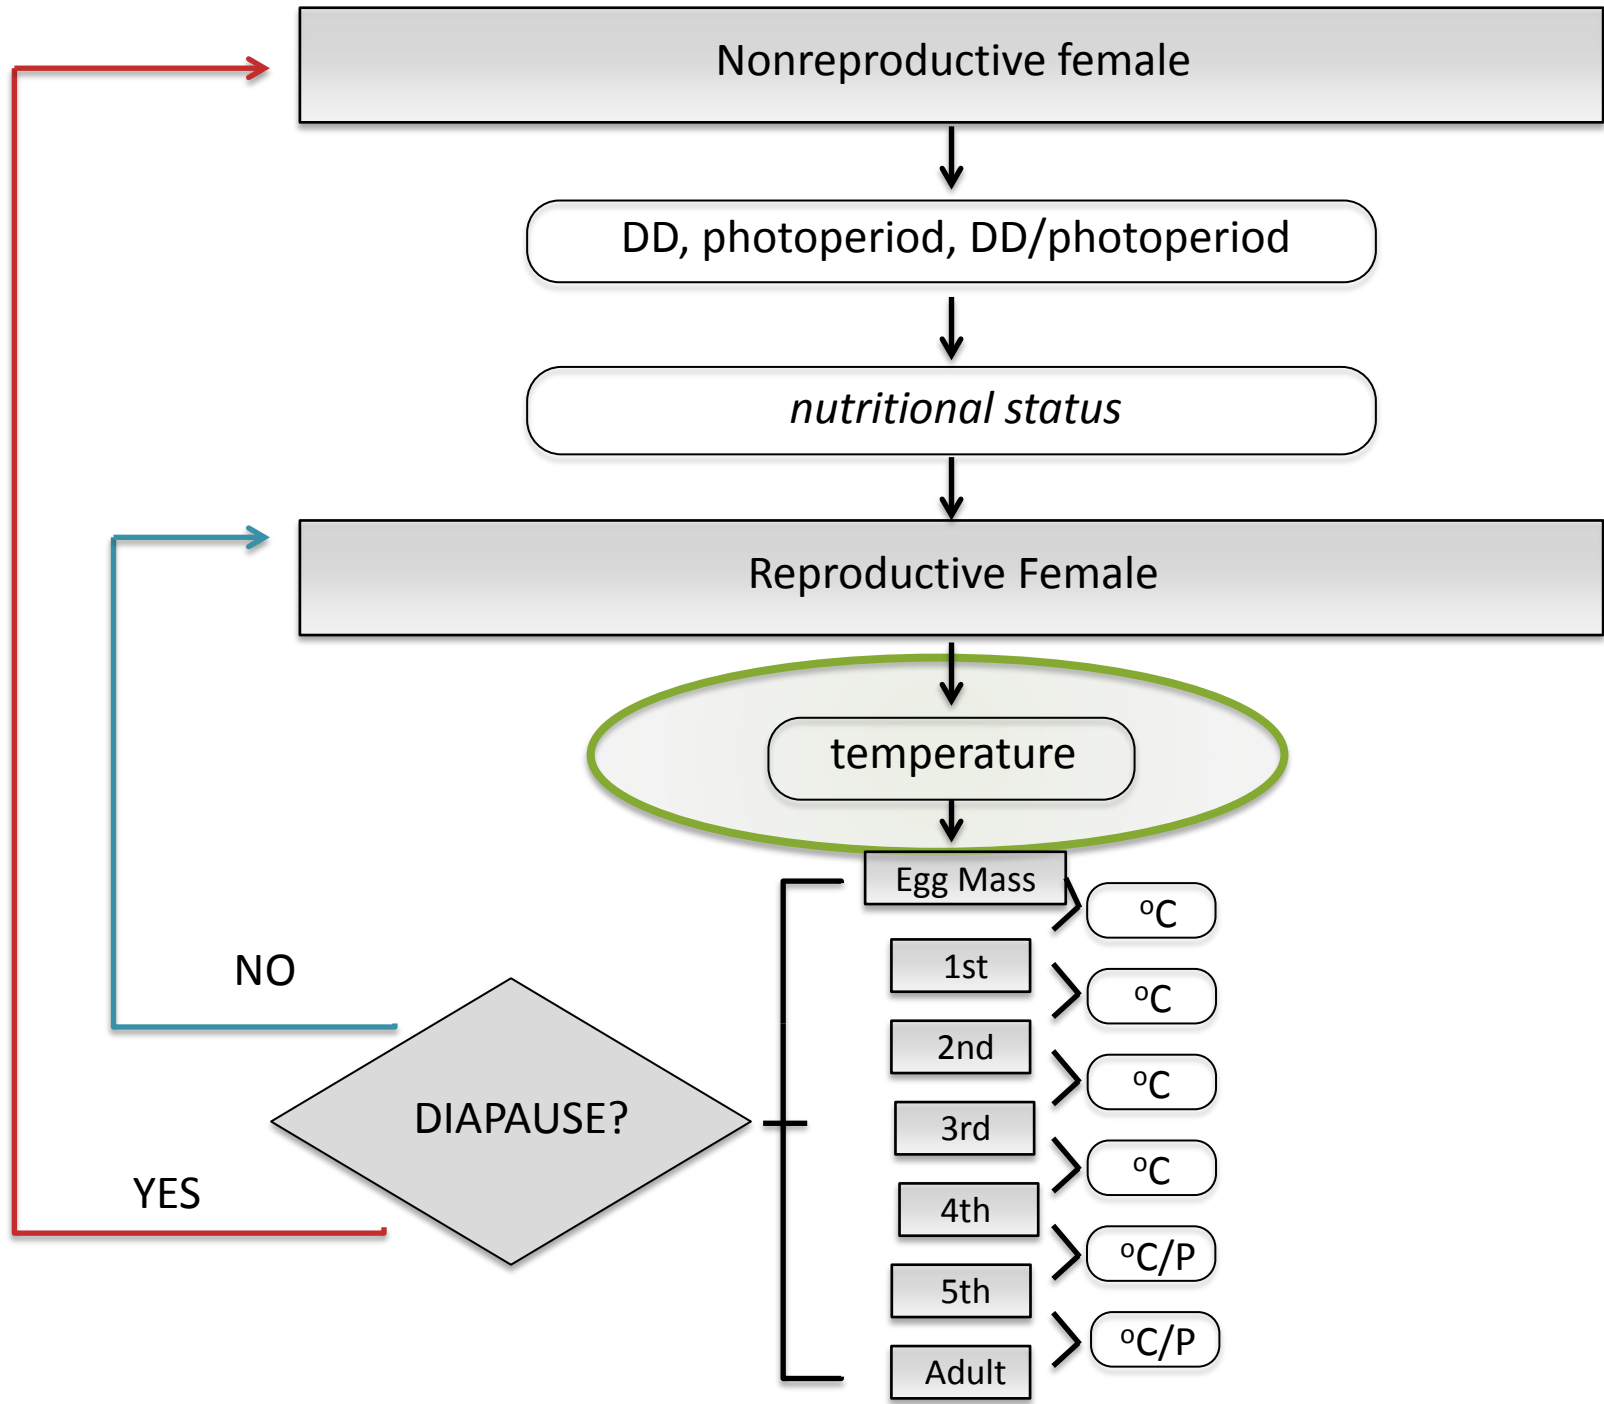

Describing Seasonality

- Seasonality through direct sampling methods
 - Visual or beat samples
 - Blacklight traps
 - Pheromone traps
- Investigate female reproduction
 - Reproductive ranking system
 - Field collected individuals

Project Number of Generations

- *Halyomorpha halys* voltinism is both temperature and photoperiod dependant
- Chen et al. 2011 utilized Mont Carlo approximations for grape berry moth
 - Voltinism is influenced by degree day accumulations prior to photoperiod conditions for diapause induction
- Assumes that development and diapause are functions of temperature and photoperiod
- Individual based
 - Diapause termination
 - Degree day development
 - Diapause induction

S. Chen, P. C. Tobin, M. C. Saunders, and S. J. Fleischer. 2011. Projecting insect voltinism under high and low greenhouse gas emission conditions. Environ. Entomol. 40: 505-515

Model Testing and Validation

1. Refine the DD requirements for female maturation
 - 16:8 photoperiod
 - Temperatures 20-33°C
2. Field collection of females from April – October
 - Bridgeton, NJ; Allentown, PA; Kearneysville, WV; Biglerville, PA
 - Rough dissections of females from diapause and host plants
 - Assign to a ranking system
3. Cage studies

Time to Oviposition

- Original study performed at 25°C suggested 13.35 day preoviposition period
- 148 DD
- Evaluate the accuracy of this by studying time to oviposition at multiple temperatures

“Preliminary” Pre-Oviposition Data 2012

BMSB Female Reproductive System

Reproductive Ranks

1 = Previtellogenic, oocytes are undifferentiated or differentiated without oocyte development

2* = Previtellogenic, one or more oocytes are developed

3 = Vitellogenic, proximal oocyte is developed

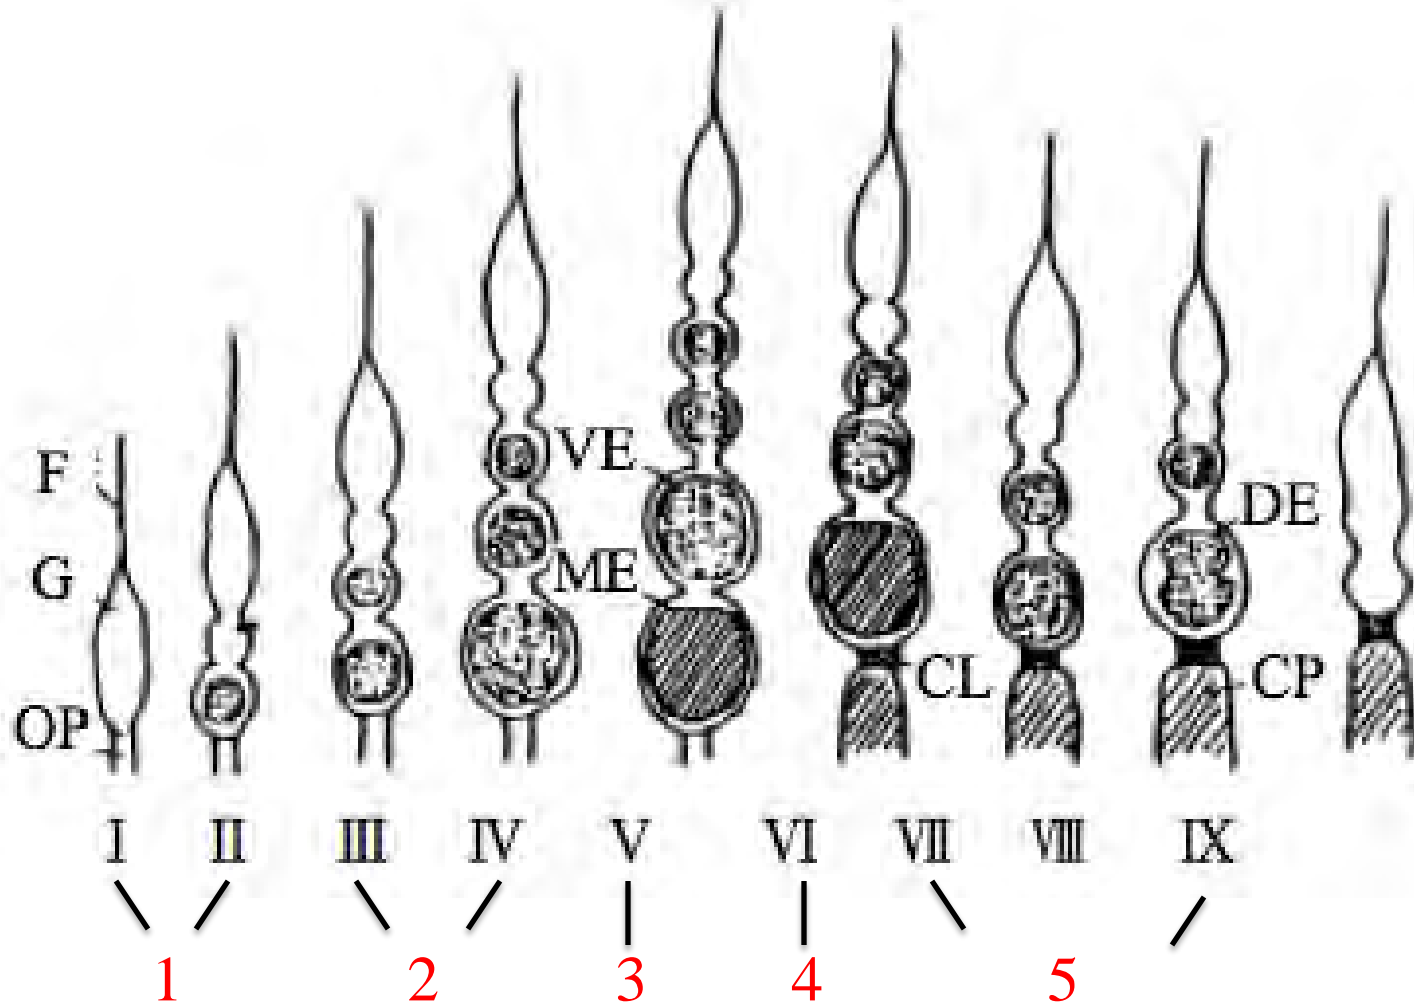

4 = Vitellogenic, oocytes are developed, at least one lateral oviduct has a descended oocyte

5 = Post-vitellogenic, oocytes are degrading, oocytes distended

** a female that has oviposited previously (i.e. CL present) cannot be previtellogenic, if oocytes/follicles are (re)developing she is a 3.*

Katayama et al. 1993 ranking system

Nielsen ranking system (in red)

2007

- 1 - Previtellogenic (early)
- 2 - Previtellogenic (late)
- 3 - Vitellogenic (early)
- 4 - Vitellogenic (late)
- 5 - Postvitellogenic

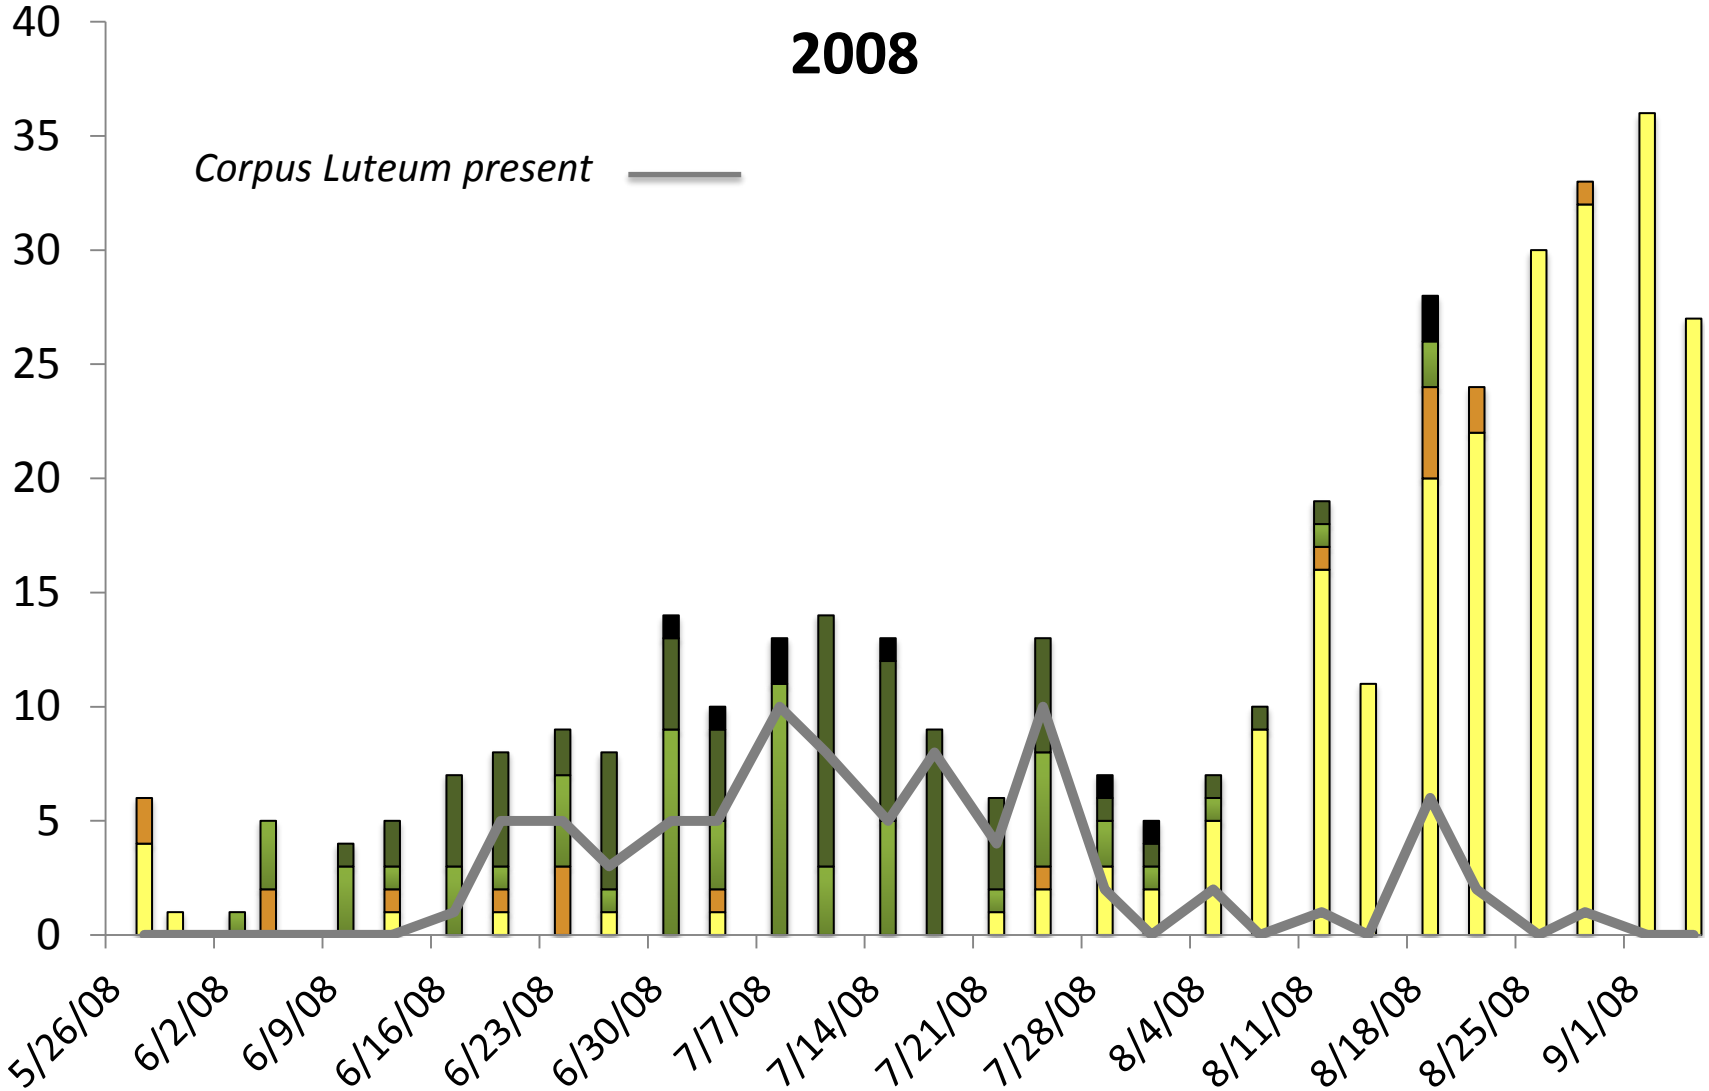

2008

2008

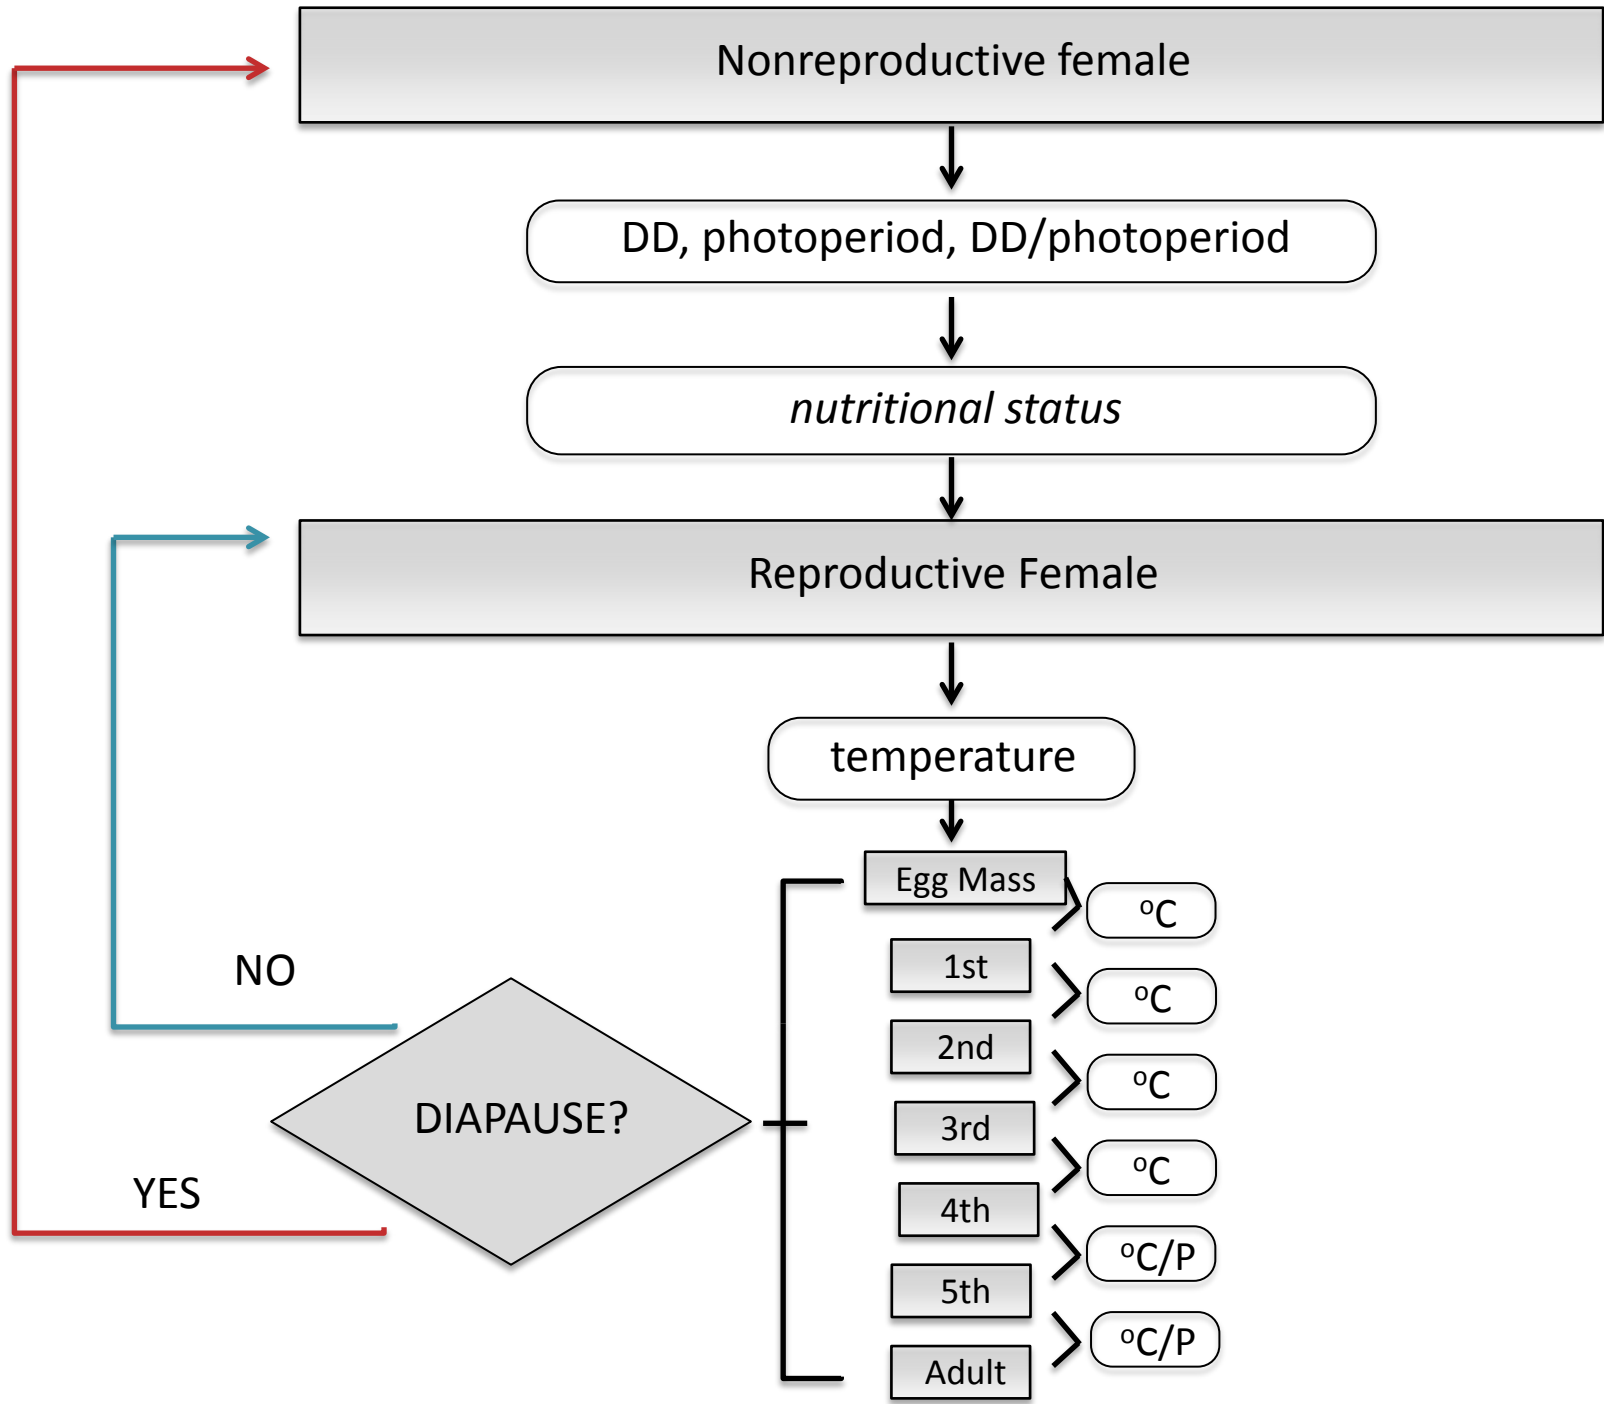

Corpus Luteum present —

Number of females per reproductive rank

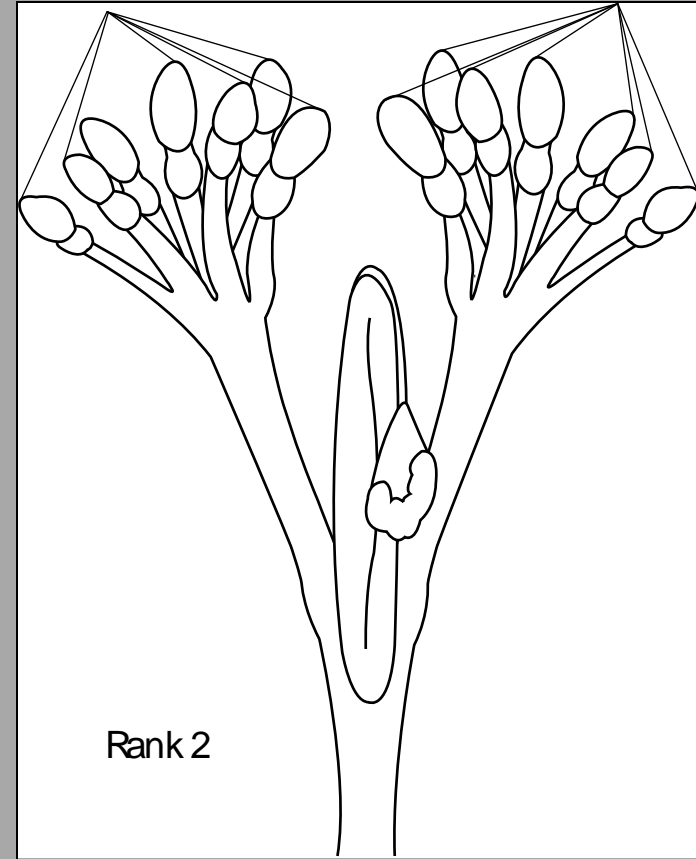

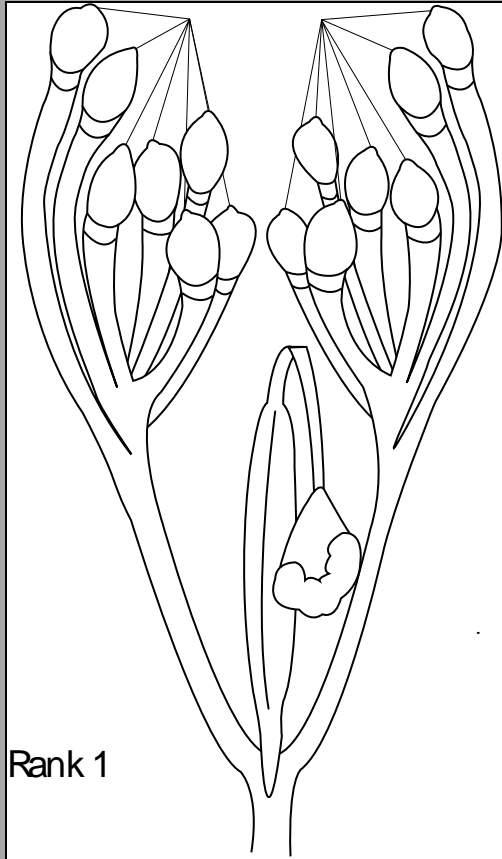

Expected Outcomes

- Refine the pre-oviposition period
- Identify appropriate biofix
- Identify number of generations based on female reproductive physiology
- Model the number of generations to predict BMSB generations in each area and as populations spread or temperatures warm

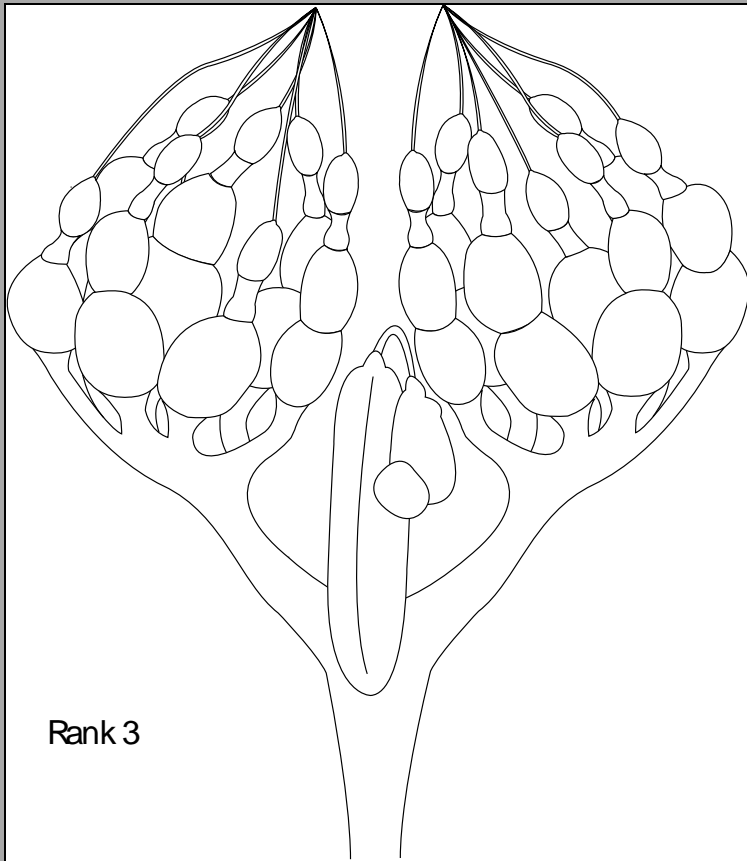

Seasonal Reproductive Development

Rank 1: undeveloped oocytes or one immature oocyte per ovariole

Rank 2: >1 Immature oocyte per ovariole

Seasonal Reproductive Development

Rank 3: At least 1 mature oocyte per ovariole

Rank 4: Mature oocytes + 1 oocyte in lateral oviduct

Rank 5: Post-vitellogenic females, ovaries distended, oocytes degenerating

Stage 1 – immature oocytes, unmated, spermatheca is clear and skinny

Stage 3 – 2 mature oocytes per ovariole, mated, CL present
