

Abiotic factors and the role they play in BMSB egg mass sterilization and survivorship

Christopher M. Taylor

Peter L. Coffey

Galen P. Dively

G. Hamilton, Rutgers

Previously...

- 2 species of bacterial symbionts have been detected from BMSB dissections
 - A Gammaproteobacteria in the genus *Pantoea*
 - Focus is on this species, which is smeared on the EM for nymphal acquisition post-eclosion
 - Identified on the egg mass surface as well as within the midgut crypts
 - A species of *Wolbachia*

M. Raupp

Previously...

- Our work has confirmed that experimental removal of the symbiont has negative effects on BMSB survival, development, and fecundity

The screenshot shows the top portion of a PLOS ONE research article page. At the top right, there are links for 'plos.org', 'create account', and 'sign in'. The PLOS ONE logo is on the left, followed by navigation links for 'Subject Areas', 'For Authors', and 'About Us'. A search bar is located on the right side of the header. Below the header, the article is identified as 'RESEARCH ARTICLE' and includes icons for 'OPEN ACCESS' and 'PEER-REVIEWED'. The article title is 'The Importance of Gut Symbionts in the Development of the Brown Marmorated Stink Bug, *Halyomorpha halys* (Stål)'. The authors listed are Christopher M. Taylor, Peter L. Coffey, Bridget D. DeLay, and Galen P. Dively. The publication date is March 05, 2014, and the DOI is 10.1371/journal.pone.0090312. On the right side of the article preview, the number of views is displayed as 209.

The Importance of Gut Symbionts in the Development of the Brown Marmorated Stink Bug, *Halyomorpha halys* (Stål)

Christopher M. Taylor, Peter L. Coffey, Bridget D. DeLay, Galen P. Dively

Published: March 05, 2014 • DOI: 10.1371/journal.pone.0090312

Objectives

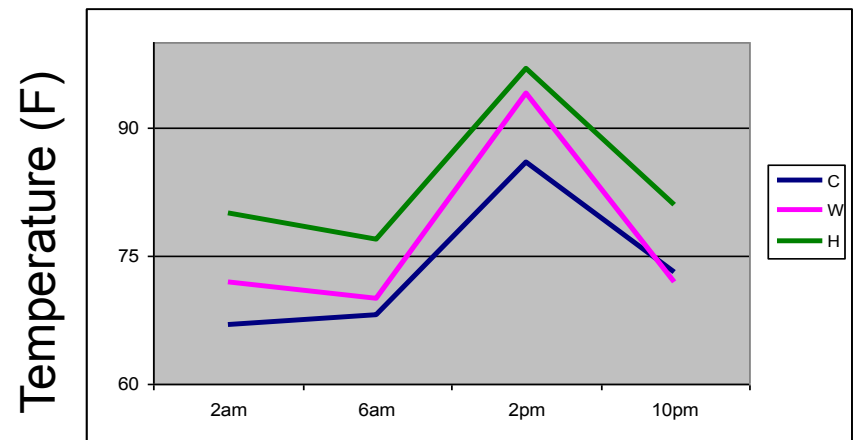

- Previously removed the symbionts chemically to determine host reliance
- Now the goal is to determine whether abiotic factors impact the symbionts in a similar way

Materials/Methods: Field Condition Chambers

- Mimicked 3 summer day conditions from Beltsville Research Farm
 - Control: 'Average temperature & high humidity'
 - Warm: 'Warm temperature & moderate humidity'
 - Hot: 'Hot temperature & low humidity'

Materials and Methods: EM Treatment Protocol

- 30 EMs collected from colony and **left on plants** on which they were laid
- Randomly assigned to 1 of 3 treatments (Control, Warm, and Hot)
- Only exposed to mimicked field condition chambers **until eclosion**, and then plants were removed and EM's reared at 25 Celsius, 75%humidity, 16:8 L:D cycle until the adult stage

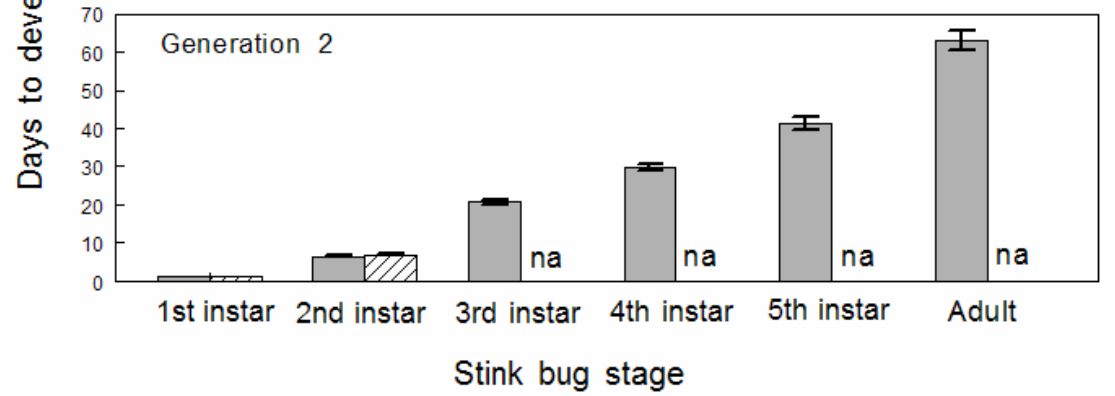

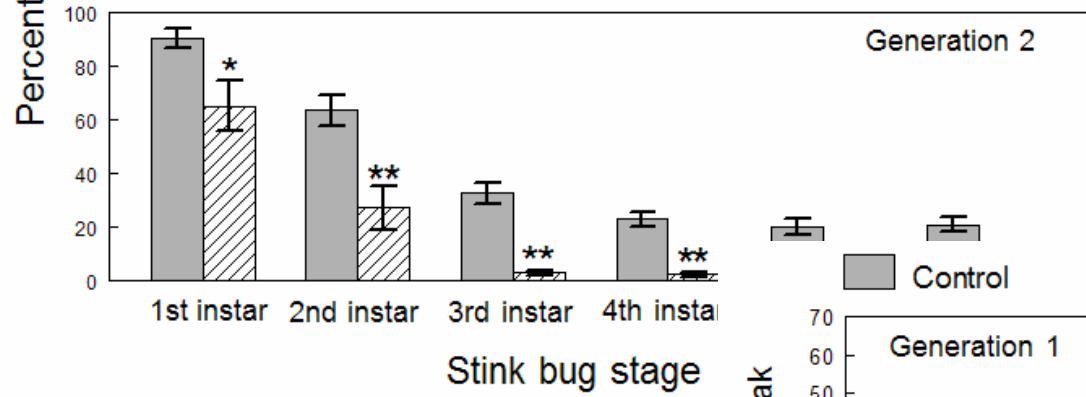

Results: Hatch Rate

- Control: 96.7% hatch rate
- Warm: 96.3% hatch rate
- Hot: 40% hatch rate

	DF	<i>p</i>
C vs. W	27	.9823
C vs. H	27	<.0001
W vs. H	27	<.0001

Results: Survival/Development Across Instars 1-5 (Control vs. Warm)

Results:

Adult eclosion rate by treatment

	Avg # Adults/EM
Control	4.8
Warm	2.2
Hot	1.4

	Num DF	Den DF	F	<i>p</i>
Trt	2	26.7	.69	.5094
Day	74	1839	4.62	<.0001
DxT	131	1832	1.62	<.0001

Results:

Adult eclosion rate by treatment

- Control: 68 days to peak of 48 adults
- Warm: 72 days to peak of 22 adults
- Hot: 58 days to peak of 14 adults

	DF	<i>p</i>
C vs. W	34.2	.0142
C vs. H	34.2	.0018
W vs. H	34.2	.4319

Conclusions

- Although there weren't significant differences in survivorship and development between C vs. W treatments until the adult stage, graphed data suggests a trend similar to that of the chemical sterilization results
- The high degree of variability in the data suggests that there are factors we aren't taking into account (such as location of egg mass on plant?)
 - Microclimate is likely playing an important role, but quantifying this is difficult

Conclusions (cont'd)

- Despite the variability, there was a significant interaction effect between treatment and time to peak adult production across treatments
- Dilip Venugopal's work has shown that on regional spatial scales, temperature is the driving force that influences BMSB population numbers
 - Does this just affect the stink bugs themselves or the symbionts that they rely on as well?

Unfinished work

- qPCR analysis of adults from 3 treatments to determine whether symbiont load is lower in W and H treatment
- Effects of humidity alone
 - Lower humidity negatively impacts the eggs and hatch rate (egg desiccation?)
- Effects of temperature alone
 - Higher temperatures don't affect hatch rate (to a certain point) but final adult counts differ

Questions?
